(57) **ABSTRACT**

An assembly (1000) includes a substrate (1002) and a heat
emissive electrical component (1001) disposed on the sub-
strate. A shield (1003) is disposed on the substrate, thereby
enclosing the heat emissive electrical component. A display
assembly (101) is disposed above the shield. A compressible
pad (1004) is disposed between the shield and the display
assembly. The compressible pad defines an aperture (1005)
above the heat emissive electrical component. The aperture
can have dimensions that are a function of a shield area and a
heat emissive electrical component area.

ELECTRONIC DEVICE ASSEMBLY WITH COMPRESSION GASKET

BACKGROUND

1. Technical Field

This disclosure relates generally to electronic devices, and more particularly to electronic devices employing compression devices.

2. Background Art

“Intelligent” portable electronic devices, such as smart phones, tablet computers, and the like, are becoming increasingly powerful computational tools. Moreover, these devices are becoming more prevalent in today’s society. For example, not too long ago a mobile telephone was a simplistic device with a twelve-key keypad that only made telephone calls. Today, “smart” phones, tablet computers, personal digital assistants, and other portable electronic devices not only make telephone calls, but also manage address books, maintain calendars, play music and videos, display pictures, and surf the web.

As the capabilities of these electronic devices have progressed, so too have their user interfaces. Prior keypads having a limited number of keys have given way to sophisticated user input devices such as touch sensitive screens or touch sensitive pads. Touch sensitive displays include sensors for detecting the presence of an object such as a finger or stylus. By placing the object on the touch sensitive surface, the user can manipulate and control the electronic device without the need for a physical keypad.

Touch sensitive electronic devices have drawbacks in that the sophisticated displays can be prone to damage. Mechanical and thermal shock can damage a display, potentially rendering it inoperable. It would be advantageous to have an electronic device with a display that is more resistant to such stresses.

BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying figures, where like reference numerals refer to identical or functionally similar elements throughout the separate views and which together with the detailed description below are incorporated in and form part of the specification, serve to further illustrate various embodiments and to explain various principles and advantages all in accordance with the present disclosure.

FIGS. 1 and 2 illustrate an explanatory electronic device configured in accordance with one or more embodiments of the disclosure.

FIG. 3 illustrates a schematic block diagram of an explanatory electronic device configured in accordance with one or more embodiments of the disclosure.

FIG. 4 illustrates an exploded view of an explanatory electronic device configured in accordance with one or more embodiments of the disclosure.

FIG. 5 illustrates a sectional view of a mechanical stack-up for one illustrative electronic device configured in accordance with one or more embodiments of the disclosure.

FIG. 6 illustrates one explanatory shield configured in accordance with one or more embodiments of the disclosure.

FIG. 7 illustrates a perspective view of an explanatory compression device configured in accordance with one or more embodiments of the disclosure.

FIGS. 8 and 13 illustrate a plan and sectional view of an explanatory compression device configured in accordance with one or more embodiments of the disclosure.

2

FIG. 9 illustrates an explanatory assembly configured in accordance with one or more embodiments of the disclosure.

FIG. 10 illustrates another explanatory assembly configured in accordance with one or more embodiments of the disclosure.

FIG. 11 illustrates heat dissipation devices enclosed by a shield in accordance with one or more embodiments of the disclosure.

FIG. 12 illustrates various embodiments of the disclosure.

Skilled artisans will appreciate that elements in the figures are illustrated for simplicity and clarity and have not necessarily been drawn to scale. For example, the dimensions of some of the elements in the figures may be exaggerated relative to other elements to help to improve understanding of embodiments of the present disclosure.

DETAILED DESCRIPTION

Embodiments of the disclosure are now described in detail. Referring to the drawings, like numbers indicate like parts throughout the views. As used in the description herein and throughout the claims, the following terms take the meanings explicitly associated herein, unless the context clearly dictates otherwise: the meaning of “a,” “an,” and “the” includes plural reference, the meaning of “in” includes “in” and “on.” Relational terms such as first and second, top and bottom, and the like may be used solely to distinguish one entity or action from another entity or action without necessarily requiring or implying any actual such relationship or order between such entities or actions. Also, reference designators shown herein in parenthesis indicate components shown in a figure other than the one in discussion. For example, talking about a device (10) while discussing figure A would refer to an element, 10, shown in figure other than figure A.

Consumers of electronic devices frequently prefer thinner, sleeker form factors. At the same time, these consumers generally want higher power processors for increased overall performance. It is axiomatic that a more powerful microprocessor, for example, generally dissipates more thermal energy than does a processor having the same form factor and operating at a slower speed. Accordingly, providing a higher power processor in a thinner device is problematic in that the device can become hot. Moreover, too much thermal dissipation into a display assembly, such as an organic light emitting diode display assembly for example, can compromise its reliability.

Embodiments of the present disclosure provide a solution to this problem by providing an assembly having superior thermal performance without the need for making the device thicker or sacrificing processing power. Additionally, embodiments of the present disclosure provide increased structural stability to the overall electronic device, thereby allowing the device to withstand higher mechanical stresses without component damage.

In one embodiment, to make the overall device thinner along the z-axis (where the x and y axes define the major faces of the device), a compressible pad is disposed between a shield attached to a circuit substrate so as to cover a heat emissive electrical component disposed on the substrate and a display assembly. Examples of heat emissive electrical components include microprocessors, control circuits, digital logic circuits, application specific integrated circuits, and so forth. Illustrating by example, in one embodiment, an assembly includes a substrate, a heat emissive electrical component disposed on the substrate, and a shield disposed on the sub-

strate enclosing the heat emissive electrical component. A compressible pad is then disposed between a display assembly and the shield.

So as to avoid thermal transfer from the heat emissive electrical component through the shield and compressible pad to the display assembly, in one embodiment the compressible pad defines an aperture above the heat emissive electrical component. In one embodiment the aperture has dimensions that are a function of a shield area, a heat emissive electrical component area, or combinations thereof. The inclusion of the aperture improves thermal performance by removing a thermal conduit between the heat emissive electrical element and the display.

In prior art systems, solid compressible devices may be positioned between hot components and the display. This is less than ideal from a thermal perspective, as the compressible device can be in significant compression and does not effectively deter thermal transfer between the hot components and the display. Experimental testing has shown that heat transfer is increased with compression of the compression device. Said differently, the greater the device is compressed, the better it acts as a conductor of heat straight from the hot component to the display.

Embodiments of the disclosure avoid this malady by providing a chamber disposed between the display and shields disposed over hot components. In some embodiments, a heat spreader can then be disposed atop the shield or deposited on a major face of the compressible pad to further help draw heat away in the x and y dimensions. Experimental testing has shown that air is a relatively poor thermal conductor and transfers less heat than a prior art, compressed, compression device.

Embodiments of the disclosure do not place arbitrary apertures in compressible pads, however, as doing so can exacerbate the susceptibility to mechanical stress noted above. If random apertures are placed in a compressible pad, their inclusion can pose problems for display mechanical strains and substrate mechanical strains.

To solve this issue, in one embodiment the aperture has dimensions that are related to shield area, heat emissive electrical component area, or combinations thereof. In effect, by correlating the size of the aperture to both the size of the shield and the size of the thermal components disposed beneath the shield, the apertures are strategically aligned over heat generating components to not only improve resistance of the display to mechanical stress, but to improve the structural stability of the overall device compared to prior art designs using solid compression devices.

In one embodiment, the aperture is designed to be as large as possible while still allowing the compressible pad to support the shield perimeter. Such an embodiment provides a small insulating window or chamber within the shield perimeter that is disposed directly between the display and the heat emissive electrical component. Accordingly, such an embodiment maximizes the amount of air directly over the heat emissive electrical component without compromising mechanical stress resistance, thereby reducing heat transfer to the display while still maintaining good support of the shield. Embodiments of the disclosure effectively control substrate strains about the shield. The display assembly retains sufficient compression area of the compressible pad along its rear face to resist mechanical stress.

Embodiments of the disclosure provide a preferred construction for electronic devices having display devices arranged directly above shields with a compressible pad disposed therebetween. Embodiments of the disclosure provide universal compressible pad coverage behind the display,

other than within the perimeter of the aperture or apertures, to provide desirable strain support for the display. Embodiments of the disclosure provide universal compressible pad support of the substrate components and shield assembly, as the aperture is strategically shaped to still allow for perimeter support of the shield, effectively controlling for strains in this area. Embodiments of the disclosure provide optimized thermal performance, even more so when heat-spreading material is added to the compressible pad with an air chamber disposed directly over heat emissive electrical components.

Turning now to FIG. 1, illustrated therein is one embodiment of an electronic device **100** configured in accordance with one or more embodiments of the disclosure. The explanatory electronic device **100** of FIG. 1 is shown as a smart phone for illustrative purposes. However, it will be obvious to those of ordinary skill in the art having the benefit of this disclosure that other electronic devices may be substituted for the explanatory smart phone of FIG. 1. For example, the electronic device **100** may be configured as a palm-top computer, a tablet computer, a gaming device, wearable computer, a media player, or other device.

A user **113** is holding the electronic device **100**. The operating system environment, which is configured as executable code operating on one or more processors or control circuits of the electronic device **100**, has associated therewith various applications or "apps." Examples of such applications shown in FIG. 1 include a cellular telephone application **102** for making voice telephone calls, a web browsing application **105** configured to allow the user **113** to view webpages on the display assembly **101** of the electronic device **100**, an electronic mail application **106** configured to send and receive electronic mail, a shopping application **107** configured to permit a user to shop for goods and services online, and a camera application **108** configured to capture still (and optionally video) images. These applications are illustrative only, as others will be obvious to one of ordinary skill in the art having the benefit of this disclosure.

The display assembly **101** of the electronic device **100** is configured as an organic light emitting diode display. An organic light emitting diode display is one type of display assembly **101** suitable for use with the disclosure, and will accordingly be used for explanatory purposes in this disclosure. However, it should be noted that other types of displays, including liquid crystal displays, would be obvious to those of ordinary skill in the art having the benefit of this disclosure.

In one embodiment the display assembly **101** comprises two substrate layers having a liquid crystal or organic polymer disposed therebetween. In the case of an organic light emitting diode layer, a film of organic material will be disposed between the two substrate layers. Each substrate layer is coupled to the other by a seam disposed about a periphery of the display assembly **101**. In the case of an organic light emitting diode display, the seam disposed about the periphery is formed by fusing two glass substrates together with a fused weld known as a "frit." A frit is a ceramic composition that is thermally fused between layers of glass to form a seam or seal between those two substrates. Experimental testing has shown the frit forming the seam is very brittle. Moreover, testing has shown that the frit forming the seam fractures easily allowing the glass substrates to separate in a cleavage mode. The organic film sealed between the glass substrates and the frit then leaks out, rendering the display inoperable. The seam serves as a lateral boundary for the liquid crystal, organic polymer, or other material disposed between the substrate layers. The seam both holds the substrate layers

5

together and keeps the liquid crystal, organic polymer, or other material disposed between the substrate layers from escaping.

Embodiments of the disclosure advantageously work to prevent cleavage mode failure of the seam by providing a compressible pad that is disposed between the display and an underlying shield to apply a compression force against the display to preload the display against one of the housing members of the device. Accordingly, the compressible pad serves as a clamping member to prevent fit cleavage failures. This will be explained in more detail below.

The explanatory electronic device **100** of FIG. **1** includes two housing members. An upper housing member **103** is disposed about the periphery of the display assembly **101**. As shown in FIG. **2**, a lower housing member **203** forms the backside of the electronic device **100** in this illustrative embodiment. Features can be incorporated into the housing members, including the buttons **109, 110, 111, 112** disposed along the upper housing member **103** shown in FIG. **1**, or the camera **201**, speaker port **202**, or audio jack **204** shown in FIG. **2**.

Turning now to FIG. **3**, illustrated therein is the electronic device (**100**) shown as a schematic block diagram **300**. The schematic block diagram **300** illustrates one embodiment of internal circuitry, software modules, firmware modules, and other components in that can be included in an explanatory electronic device (**100**) configured in accordance with embodiments of the disclosure. While this illustrative internal circuitry is directed to a generic electronic device, note that it could be readily adapted to any number of specific devices.

As shown in the schematic block diagram **300**, a control circuit **301** is operable with the display assembly **101**, which is configured with touch-sensitive capabilities in this illustrative embodiment. The control circuit **301**, which may be a microprocessor, programmable logic, application specific integrated circuit device, or other similar device, is capable of executing program instructions. The program instructions may be stored either in the control circuit **301** or in a memory **302** or other computer readable medium operable with the control circuit **301**. The memory **302** can also store executable code corresponding to the various applications **303** that are operable on the electronic device (**100**), such as those described above with reference to FIG. **1**.

The control circuit **301** is configured, in one embodiment, to operate the various functions of the electronic device (**100**). The control circuit **301** can execute software or firmware applications stored in memory **302** to provide device functionality. In one embodiment, the control circuit **301** is configured to be operable with a display driver **306** to effect and control presentation of information on the display assembly **101**.

Coupled to, and operable with, the controller is the display assembly **101**. The explanatory display assembly **101** of FIG. **1** is shown as a plurality of layers. While this illustrates one embodiment of a touch sensitive display, it will be clear to those of ordinary skill in the art having the benefit of this disclosure that embodiments of the disclosure are not so limited. Numerous other display configurations, be they touch sensitive or not, can be substituted without departing from the spirit and scope of the disclosure.

In the illustrative embodiment of FIG. **3**, the four layers of the display assembly **101** are shown, although other optional layers could be included as needed. Starting from the top, a fascia layer **210** is provided. The fascia layer **210** may be manufactured from glass or a thin film sheet. As used herein, a "fascia" is a covering or housing, which may or may not be detachable. Suitable materials for manufacturing the cover

6

layer include clear or translucent plastic film, glass, plastic, or reinforced glass. Reinforced glass can comprise glass strengthened by a process such as a chemical or heat treatment. The fascia layer **210** may also include an ultra-violet barrier. Such a barrier is useful both in improving the visibility of display assembly **101** and in protecting internal components of the electronic device.

Beneath the fascia layer **210** is the capacitive touch sensor layer **211**. The capacitive touch sensor layer **211** is included to provide the touch sensing function. The capacitive touch sensor layer **211**, which can be constructed by depositing small capacitive plate electrodes on a transparent substrate, is configured to detect the presence of an object, such as a user's finger or stylus, near to or touching the display assembly **101**. Circuitry operable with or disposed within the control circuit **301** is configured to detect a change in the capacitance of a particular plate combination on the capacitive touch sensor layer **211**. The capacitive touch sensor layer **211** may be used in a general mode, for instance to detect the general proximate position of an object relative to the touch sensitive display. The capacitive touch sensor layer **211** may also be used in a specific mode, where a particular capacitor plate pair may be detected to detect the precise location of an object along length and width of the touch sensitive display. Note that the capacitive touch sensor layer **211** is a particular implementation of an electromagnetic field sensor, and other types of electromagnetic field sensors, such as a magnetic field sensor, can replace the capacitive field sensor.

Note that while the capacitive touch sensor layer **211** and the fascia layer **210** are shown as separate layers in FIG. **3** for illustrative purposes, in many embodiments they will be integrated into a single element to achieve a thinner overall form factor of the electronic device (**100**). Accordingly, in one embodiment the capacitive touch sensor layer **211** is integrated with the fascia layer **210** by depositing the capacitor plate electrodes of the capacitive touch sensor layer **211** directly upon the fascia layer **210**. For example, indium tin oxide defining the capacitor plate electrodes can be laminated directly to the underside of the fascia layer **210**.

Disposed beneath the capacitive touch sensor layer **211** is the display layer **212**. The display layer **212** houses the active material that controls the presentation operation of the display assembly **101**. For example, where the display layer **212** is an organic light emitting diode layer, the display layer **212** will comprise two substrate layers sealed together at a seam disposed along a periphery of each substrate layer. The substrate layers can have clear control electrodes disposed thereon. For example, the electrodes can be manufactured by depositing indium tin oxide along the substrates. One or more organic thin films are disposed between the substrates and within the seam. When electrical current is applied to the electrodes, the organic films emit light to present information on the display assembly **101**.

Were the display layer **212** not an organic light emitting diode layer, but rather another technology such as a liquid crystal layer, additional layers may be required. For example, a backlighting layer may need to be disposed beneath a liquid crystal layer because liquid crystal, unlike organic light emitting diode films, do not produce light.

Beneath the active display layer is an optional reflector **213**. The reflector **213** can reflect light generated by the display layer **212** (or a backlighting layer were included) back out of the display assembly **101**. The reflector **213** can be manufactured from a reflective material such as polyethylene terephthalate in one embodiment.

Turning now to FIG. **4**, illustrated therein is an exploded view of one explanatory electronic device **100** configured in

accordance with one or more embodiments of the disclosure. A first housing member **103** is shown above a fascia layer **210**. The first housing member **103** defines an aperture **401**. The fascia layer **210** fits within the first housing member **103** to span and cover the aperture **401**. Some designers refer to the fascia layer **210** as a “lens,” although the fascia layer **210** generally does not include optical magnification properties.

An display assembly **101** is disposed beneath the fascia layer **210**. The illustrative display assembly **101** of FIG. **4** includes two substrate layers **404,405** sealed together at a seam **408** disposed along a periphery of each substrate layer **404,405**. As used herein, “periphery” refers to an outer region of an area or object, or in this case, an outer region disposed just within a perimeter **403** of the substrate layers **404,405**. For example, if the substrate layers **404,405** are three inches by two inches, the periphery may include portions of the substrate layers **404,405** that extend inward from the perimeter **403** two or three tenths of an inch or so.

A compression gasket **402** is then disposed between a shield **406** disposed on a circuit board **407** and the display assembly **101**. The compression gasket **402** can comprise one gasket, or multiple gaskets. The compression gasket **402** seats against the second substrate layer **405** of the display assembly **101** to provide a loading force between the display assembly **101** and the shield **406**. When a coupler **409**, shown here as a mechanical feature on the first housing member **103**, couples the first housing member **103** and the second housing member **203** together, the compression gasket **402** becomes preloaded against the display assembly **101**. This preloading, in turn, preloads the display assembly **101** against the first housing member **103**, thereby helping to prevent cleavage failures at the seam **408**.

Turning now to FIG. **5**, illustrated therein is a sectional view of the electronic device **100**. An assembly of the electronic device **100** includes a substrate **501**. In one embodiment, the substrate **501** is a printed circuit board. Other examples of substrates will be obvious to those of ordinary skill in the art having the benefit of this disclosure.

In one embodiment, a heat emissive electrical component **502** is disposed on the substrate **501**. The heat emissive electrical component **502** can be any of a number of electronic devices that dissipate electrical energy as heat. Illustrating by example, the heat emissive electrical component **502** can be the control circuit (**301**) of FIG. **3**. As noted above, the heat emissive electrical component **502** can be any of a microprocessor, programmable logic, application specific integrated circuit device, or other similar device. Other heat emissive electrical components will be obvious to those of ordinary skill in the art having the benefit of this disclosure. In one embodiment, the heat emissive electrical component **502** has a heat dissipation greater than one watt. In one embodiment, the heat emissive electrical component **502** has a major component dimension greater than ten millimeters. This dimension and heat dissipation would be common when the heat emissive electrical component **502** is a microprocessor, for example.

In one embodiment, a shield **503** is disposed on the substrate **501**. In one embodiment, the shield **503** encloses the heat emissive electrical component **502**. As used herein, “enclose” means to surround on sides. Accordingly, the shield **503** and the substrate **501** completely enclose the heat emissive electrical component **502** in this illustrative embodiment.

A display assembly **101** is disposed above the shield **503**. In one embodiment, a compression gasket **402** is disposed between the shield **503** and the display assembly **101**. In one embodiment, the compression gasket **402** defines an aperture **504** above the heat emissive electrical component **502**. As

noted above, in one embodiment the aperture **504** has dimensions that are a function of a shield area, a heat emissive electrical component area, or combinations thereof. For example, in one embodiment the aperture **504** has a major aperture dimension greater than 0.9 times the major component dimension. In one embodiment, the major aperture dimension is greater than the major component dimension. In one embodiment, the major aperture dimension less than 1.2 times the major component dimension.

In one embodiment, the major shield dimension is greater than the major aperture dimension. In one embodiment, the major shield dimension is more than one millimeter greater than the major aperture dimension. In one embodiment, the major shield dimension is less than 1.2 times the major component dimension.

In one embodiment, the aperture **504** has a substantially rectangular perimeter with radiused corners. In other embodiments, the aperture **504** can take other shapes, including circular, triangular, polygonal, free form, and so forth. The shape of the aperture **504** can be determined from the application or heat emissive electrical component **502** with which the shield **503** is used.

In one embodiment, the compression gasket **402** applies a loading force applied between the display assembly **101** and the shield **503**. In one embodiment, the loading force is a function of a difference between the major shield dimension and the major aperture dimension. In one embodiment, the loading force is further a function of a compression coefficient of the compressible pad. As shown in FIG. **5**, in one embodiment, the first housing member **103** and the second housing member **203** are disposed opposite the assembly to compress the compression gasket **402** between the shield **503** and the display assembly **101**.

Turning now to FIG. **6**, illustrated therein is one embodiment of a shield **503** configured in accordance with one or more embodiments of the disclosure. Electromagnetic shields are frequently found in radio frequency (RF) electronic devices or in other devices that may be sensitive to electromagnetic emissions. Shields are commonly used to isolate sensitive components residing on a circuit board. Shields can also serve a mechanical function, adding stability and reinforcing structure to circuit boards, displays, and housing members as well. For example, the shield **503** can be used to provide necessary stiffness, rigidity, and or support to a circuit board or other substrate. This is especially true when using compression gaskets as described below. In one or more embodiments, shields are made from a metal or metallized member that has a planar top surface and planar sidewalls extending orthogonally from each edge of the top surface. The bottom ends of the sidewalls may include feet or flanges so that the shield can be soldered to the circuit board.

As shown, the shield **503** has a substantially planar top surface **601** and substantially planar sidewalls **602,603,604** extending orthogonally from each edge of the substantially planar top surface **601**. This particular shield **503** includes flanges **605,606,606**.

In one embodiment, the shield **503** comprises a one-piece structure. In another embodiment, the shield **503** comprises a two-piece structure. The illustration in FIG. **5** illustrates a one-piece structure, where the planar top surface **601** and substantially planar sidewalls **602,603,604** are formed from a unitary piece of metal. In a two-piece structure, the substantially planar top surface **601** and the substantially planar sidewalls **602,603,604** are separate. The substantially planar sidewalls **602,603,604** can be soldered or otherwise coupled to a substrate. Once this is complete, the substantially planar top surface **601** can be attached to the substantially planar

sidewalls **602,603,604**. In one embodiment, the substantially planar top surface **601** is configured to snap onto the substantially planar sidewalls **602,603,604**. Other embodiments of shields described below can likewise be configured as either one-piece or two-piece shields.

In one or more embodiments, shield **503** can be used to shield integrated circuits or other electronic components from electromagnetic emissions. The shield **503** can be soldered or otherwise coupled to a circuit substrate so as to cover the shielded electronic components. The shield **503** is suitable for use in many different types of electronic devices. Illustrating by example, the shield **503** can be used in mobile communication devices, such as smartphones, tablet computers, and so forth. Those of ordinary skill in the art having the benefit of this disclosure will understand that mobile communication devices are merely one type of electronic device for which the shield **503** is suited, and are being used purely for illustrative purposes. Shields configured in accordance with one or more embodiments of the disclosure are certainly usable and compatible with any number of different structures and devices.

In one embodiment, the shield **503** is manufactured from a sheet metal frame. For example, in one embodiment, the shield **503** can be machine formed from cold rolled steel. In other embodiments, the shield **503** can be manufactured from cast metal. Other materials and methods of manufacture for the shield will be obvious to those of ordinary skill in the art having the benefit of this disclosure.

Turning now to FIGS. 7-8 and 13, illustrated therein is one embodiment of a compressible pad **700** configured in accordance with one or more embodiments of the disclosure. The compressible pad **700**, which can also be configured as a compression gasket in some embodiments, is manufactured from a compressible medium such as rubber or polymer. In this illustrative embodiment, compressible pad **700** has a width **704** along the x-axis **701** in a first dimension, and a length **705** along the y-axis **702** in a second dimension, which is orthogonal to the x-axis **701**. The compressible pad **700** also has a compressible thickness **706** along the z-axis **703**.

In one embodiment, the compressible pad **700** defines one or more apertures **707,708** along a major face **709**. In one or more embodiments, the number of apertures **707,708** corresponds to a number of heat generating components disposed beneath a shield. For example, in one embodiment a "heat generating component" can be a cluster of components that are closely located on a circuit board. In such an embodiment, a particular aperture **707** may correspond to multiple heat emissive electrical components. In another embodiment, a heat generating component can be a single component, such as a microprocessor. In the latter embodiment, a particular aperture **707** will correspond to a heat emissive electrical component on a one-to-one basis. This illustrative embodiment includes two apertures **707,708**. However it will be obvious to those of ordinary skill in the art having the benefit of this disclosure that other numbers of apertures, such as one, three, four, or eight, can be used without departing from the scope of the disclosure.

As noted above, in one embodiment, the apertures **707,708** have specifically designed dimensions. For example, in one embodiment, the apertures **707,708** have dimensions that are a function of a shield area, heat emissive electrical component area, or combinations thereof. In this illustrative embodiment, the apertures **707,708** are square shaped. Accordingly, the major dimensions, i.e. the length **801** and width **802** are equivalent. However, in other embodiments, the apertures **707,708** have different shapes. They can be polygonal, round,

ovular, or take free form shapes. In such embodiments, the major dimension will be the longest length, width, or diameter.

In one or more embodiments, the apertures **707,708** have a major aperture dimension greater than 0.9 times the major component dimension above which a particular aperture sits. In one embodiment, the major aperture dimension is greater than the major component dimension. In one embodiment, the major aperture dimension less than 1.2 times the major component dimension. In one embodiment, the major shield dimension is greater than the major aperture dimension. In one embodiment, the major shield dimension is more than one millimeter greater than the major aperture dimension. In one embodiment, the major shield dimension is less than 1.2 times the major component dimension.

Turning now to FIG. 9, illustrated therein is an example of an assembly **900** configured in accordance with one or more embodiments of the disclosure. As shown a heat dissipation device **901**, which here is a microprocessor, is enclosed by a shield **903** and a circuit board **902**. A compression gasket **904** is disposed above the shield **903**. The compression gasket defines a chamber **905** created by an aperture in the compression gasket **904**. As shown, the chamber **905** is axially aligned with the heat dissipation device **901** along axis **906**. A device element, such as the display assembly (**101**) of FIG. 3, would sit atop the compression gasket **904**. However, in the view of FIG. 9, the device element is not shown to make the other components viewable.

The heat dissipation device **901** has a major dimension **907**. In one embodiment, this major dimension **907** is greater than ten millimeters. The chamber **905** has a major dimension **908**. The shield **903** has a major dimension **909** as well.

In one embodiment, the major dimension **908** of the chamber **905** is greater than 0.9 times the major dimension **907** of the heat dissipation device **901**. In one embodiment, the major dimension **908** of the chamber **905** is greater than the major dimension **907** of the heat dissipation device **901**. In one embodiment, the major dimension **908** of the chamber **905** is less than 1.2 times the major dimension **907** of the heat dissipation device **901**.

As shown in FIG. 9, in this illustrative embodiment, the major dimension **909** of the shield **903** is greater than the major dimension **908** of the chamber **905**. To provide suitable support for the device element disposed above the compression gasket **904**, in one embodiment, the major dimension **909** of the shield **903** is more than one millimeter greater than the major dimension **908** of the chamber **905**. In one embodiment, the major dimension **909** of the shield **903** is less than 1.2 times the major dimension **909** of the heat dissipation device **901**.

Turning to FIG. 10, illustrated therein is another assembly **1000** configured in accordance with one or more embodiments of the disclosure. A heat emissive electrical component **1001** is disposed on a substrate **1002**. A shield **1003** is disposed on the substrate **1002**. The shield **1003** of this illustrative embodiment encloses the heat emissive electrical component **1001**.

A display assembly **101** is disposed above the shield **1003**. A compressible pad **1004** is disposed between the shield **1003** and the display assembly **101**. As with other embodiments, the compressible pad **1004** defines an aperture **1005** above the heat emissive electrical component **1001**. In one embodiment, the aperture **1005** has dimensions that are a function of a shield area, a heat emissive electrical component area, or combinations thereof.

When the assembly **1000** is assembled, the compressible pad **1004** applies loading force between the display assembly

11

101 and the shield **1003**. For example, as noted above with reference to FIG. 3, a first and second housing assemblies may “clamp” the compressible pad **1004** between the display assembly **101** and the shield **1003**. The compression modulus of the compressible pad **1004** results in a loading force—oriented outwardly—between the display assembly **101** and the shield **1003**. This loading force adds additional stability to the overall mechanical structure of the assembly **1000**. In one embodiment, the loading force is a function of a compression coefficient of the compressible pad **1004**.

An optional heat spreader **1010** is shown disposed between the compressible pad **1004** and the display assembly **101**. The heat spreader **1010** helps to transfer heat along the x-axis **701** and the y-axis **702** to prevent hot spots from forming on the shield. In other embodiments, the optional heat spreader **1010** can be disposed between the compressible pad **1004** and the shield **1003**. In one or more embodiments, the compressible pad **1004** can have a reflective material **1011** disposed on its lower major face **1012**. The reflective material **1011**, which is also optional, helps to prevent heat from reaching the display assembly **101**.

In this illustrative embodiment, the dimensions of the aperture **1005** are determined according to the following parameters:

Variables:

L_{chip} = the longer of the length (along the y-axis **702**) or the width (along the x-axis **701**) of the heat emissive electrical component **1001** (EQ. 1)

L_{cutout} = the longer of the length (along the y-axis **702**) or the width (along the x-axis **701**) of the aperture **1005** (EQ. 2)

L_{shield} = the longer of the length (along the y-axis **702**) or the width (along the x-axis **701**) of the shield **1003** (EQ. 3)

T_{shield} = the thickness (along the z-axis **703**) of the shield **1003** (EQ. 4)

$A_{overlap}$ = Area of overlap between compressible pad **1004** and the shield **1003**. (EQ. 5)

Illustrating by example, the compressible pad **1004** and shield **1003** overlap in area **1013**, but do not overlap at areal **1014**.

F_{pad} = Loading force applied by compression of the compressible pad **1004** (EQ. 6)

dx = Amount of compression of the compressible pad **1004** (EQ. 7)

E = Young's modulus for the material of the compressible pad **1004** (EQ. 8)

(Note that E is a non-linear function of dx .)

From these variables, dimensions of the aperture **1005** can be calculated, in one embodiment, as follows:

Aperture major dimension $\geq 0.9 * L_{chip}$ (EQ. 9)

$L_{shield} > L_{cutout}$ (EQ. 10)

$L_{shield} - L_{cutout} > 1 \text{ mm}$ (EQ. 10)

$L_{cutout} \leq 1.2 * L_{chip}$ (EQ. 11)

$L_{shield} \leq 1.2 * L_{chip}$ (EQ. 12)

$F_{pad} = K_{pad} * dx$ (EQ. 13)

$K_{pad} = E * A_{overlap} / dx$ (EQ. 14)

12

In the embodiment of FIG. 10, the perimeter of the aperture **1005** corresponds generally to the perimeter of the heat emissive electrical component **1001**. In this illustrative embodiment, both are substantially rectangular, but with different areas. Embodiments of the disclosure are not so limited. Turning now to FIG. 11, illustrated therein is but one example of the many different configurations possible without departing from the spirit and scope of the disclosure.

In FIG. 11, three heat dissipation devices **1101, 1102, 1103** are enclosed by a shield **1104** and a circuit board **1105**. A compression gasket **1106** is disposed between the shield **1104** and a device element (not shown), such as a display assembly (**101**). The compression gasket **1106** defines three chambers **1107, 1108, 1109** that are axially aligned with the heat dissipation devices **1101, 1102, 1103**.

Chamber **1107** is wider along a first dimension **1118** than the heat dissipation device **1101** to which it corresponds. Chamber **1107** is narrower along a second dimension **1119** than the heat dissipation device **1101**. In this embodiment, the second dimension **1119** is substantially orthogonal to the first dimension **1118**, than the heat dissipation device.

Chamber **1108** has a first perimeter shape, which in this embodiment is substantially rectangular. However, the heat dissipation device **1102** to which it corresponds has a second perimeter shape. The first perimeter shape and the second perimeter shape are different. Chamber **1108** also has a non-rectangular perimeter **1112**.

Chamber **1109** has a common dimension **1110** with the heat dissipation device **1103** to which it corresponds. Chamber **1109** also has a different dimension **1111**, orthogonal to the common dimension **1110**, than the heat dissipation device **1103**.

Turning now to FIG. 12, illustrated therein are various embodiments of the disclosure. At **1201**, an assembly comprises a substrate, a heat emissive electrical component disposed on the substrate, and a shield disposed on the substrate enclosing the heat emissive electrical component. At **1201**, the assembly also includes a display assembly and a compressible pad disposed between the shield and the display assembly. At **1201**, the compressible pad defines an aperture above the heat emissive electrical component. At **1201**, the aperture has dimensions that are a function of a shield area and a heat emissive electrical component area.

At **1202**, the aperture of **1201** has a major aperture dimension greater than 0.9 times the major component dimension. At **1203**, the major aperture dimension of **1202** is greater than the major component dimension. At **1204**, the major aperture dimension of **1202** is less than 1.2 times the major component dimension. At **1205**, the heat emissive electrical component of **1201** has a power dissipation greater than one watt. At **1206**, the heat emissive electrical component of **1201** has a major component dimension greater than ten millimeters. At **1207**, the major shield dimension of **1202** is greater than the major aperture dimension. At **1208**, the major shield dimension of **1202** is more than one millimeter greater than the major aperture dimension. At **1209**, the major shield dimension of **1202** is less than 1.2 times the major component dimension. At **1210**, a loading force is applied by the compressible pad of **1201** between the display assembly and the shield. At **1210** the loading force is a function of a difference between the major shield dimension and the major aperture dimension. At **1211**, the loading force of **1210** is further a function of a compression coefficient of the compressible pad. At **1212**, the assembly of **1201** comprises a first housing member and a second housing member disposed opposite the assembly to compress the compressible pad between the shield and the display assembly.

13

At **1213**, the compressible pad of **1201** comprises a reflective layer disposed adjacent to the shield. At **1214**, the display assembly of **1201** comprises an organic light emitting display.

At **1215**, an assembly comprises a heat dissipation device enclosed by a shield and a circuit board, a device element, and a compression gasket disposed between the shield and the device element. At **1215**, the compression gasket defines a chamber axially aligned with the heat dissipation device.

At **1216**, the device element of **1215** comprises a display. At **1217**, the assembly of **1215** has a chamber being wider along a first dimension than the heat dissipation device and narrower along a second dimension, orthogonal to the first dimension, than the heat dissipation device. At **1218**, the assembly of **1215** has a chamber having a first perimeter shape, the heat dissipation device having a second perimeter shape, the first perimeter shape and the second perimeter shape being different. At **1219**, the assembly of **1215** has a chamber having a common dimension with the heat dissipation device and a different dimension, orthogonal to the common dimension, than the heat dissipation device. At **1220**, the assembly of **1215** has a non-rectangular perimeter. Other embodiments aside from those shown in FIG. 12 will be obvious to those of ordinary skill in the art having the benefit of this disclosure.

In the foregoing specification, specific embodiments of the present disclosure have been described. However, one of ordinary skill in the art appreciates that various modifications and changes can be made without departing from the scope of the present disclosure as set forth in the claims below. Thus, while preferred embodiments of the disclosure have been illustrated and described, it is clear that the disclosure is not so limited. Numerous modifications, changes, variations, substitutions, and equivalents will occur to those skilled in the art without departing from the spirit and scope of the present disclosure as defined by the following claims. Accordingly, the specification and figures are to be regarded in an illustrative rather than a restrictive sense, and all such modifications are intended to be included within the scope of present disclosure. The benefits, advantages, solutions to problems, and any element(s) that may cause any benefit, advantage, or solution to occur or become more pronounced are not to be construed as a critical, required, or essential features or elements of any or all the claims.

What is claimed is:

1. An assembly, comprising: a substrate; a heat emissive electrical component disposed on the substrate; a shield disposed on the substrate enclosing the heat emissive electrical component; a display assembly; and a compressible pad disposed between the shield and the display assembly, the compressible pad defining an aperture above the heat emissive electrical component, the aperture having dimensions that are a function of a shield area and a heat emissive electrical component area.

14

2. The assembly of claim 1, the aperture having a major aperture dimension greater than 0.9 times a major component dimension.

3. The assembly of claim 2, the major aperture dimension greater than the major component dimension.

4. The assembly of claim 2, the major aperture dimension less than 1.2 times the major component dimension.

5. The assembly of claim 4, the heat emissive electrical component having a power dissipation greater than one watt.

6. The assembly of claim 4, the heat emissive electrical component having a major dimension greater than ten millimeters.

7. The assembly of claim 2, a major shield dimension greater than the major aperture dimension.

8. The assembly of claim 7, the major shield dimension more than one millimeter greater than the major aperture dimension.

9. The assembly of claim 7, the major shield dimension less than 1.2 times the major component dimension.

10. The assembly of claim 7, a loading force applied by the compressible pad between the display assembly and the shield a function of a difference between the major shield dimension and the major aperture dimension.

11. The assembly of claim 10, the loading force further a function of a compression coefficient of the compressible pad.

12. The assembly of claim 1, further comprising a first housing member and a second housing member disposed opposite the assembly to compress the compressible pad between the shield and the display assembly.

13. The assembly of claim 1, the compressible pad comprising a reflective layer disposed adjacent to the shield.

14. The assembly of claim 1, the display assembly comprising an organic light emitting display.

15. An assembly, comprising: a heat dissipation device enclosed by a shield and a circuit board; a device element comprising a display; and a compression gasket disposed between the shield and the device element, the compression gasket defining a chamber axially aligned with the heat dissipation device.

16. The assembly of claim 15, the chamber being wider along a first dimension than the heat dissipation device and narrower along a second dimension, orthogonal to the first dimension, than the heat dissipation device.

17. The assembly of claim 15, the chamber having a first perimeter shape, the heat dissipation device having a second perimeter shape, the first perimeter shape and the second perimeter shape being different.

18. The assembly of claim 15, the chamber having a common dimension with the heat dissipation device and a different dimension, orthogonal to the common dimension, than the heat dissipation device.

19. The assembly of claim 15, the chamber having a non-rectangular perimeter.
